KARYOTYPES OF FIVE SPECIES OF CUBAN LIZARDS

Calvin A. Porter, Ronald I. Crombie, and Robert J. Baker

In August 1988, we obtained several species of lizards from the Guantánamo Naval Base, Guantánamo (formerly Oriente) Province of Cuba. All but two individuals of these lizards were returned to the laboratory at Texas Tech University, and we prepared karyotypes from testes or bone marrow according to the procedures of Porter and Sites (1986). The remaining two lizards were karyotyped from tissue cultures (Sites et al., 1979) in the laboratory of Michael W. Haiduk at Lamar University. The lizards studied included four species of the iguanid genera Leiocephalus and Anolis, and one species of the teiid genus Ameiva. All specimens are deposited as vouchers in the herpetology collection at Texas Tech University. The karyotypes of these species are described below.

Leiocephalus.—Representatives of two species of this genus both had 12 metacentric macrochromosomes, but differed in the number of microchromosomes. Three females of L. carinatus had a diploid number of 34, with 22 microchromosomes (Fig. 1A).

Five individuals of L. rauceps (four males and one female) were examined, and all had 18 microchromosomes and a diploid number of 30 (Fig. 1B, C). In the males (Fig. 1B), one microchromosome was considerably smaller than any of the others. Examination of more than nine diakinesis cells from three of the four males showed that this chromosome formed a heteromorphic bivalent with a larger microchromosome (Fig. 2A). Secondary spermatocytes had a haploid number of 15 (Fig. 2B). The single female examined of this species (Fig. 1C) had the same
number of microchromosomes as the males, but did not have the unusually small microchromosome. These data suggest that *L. raviceps* has an XX/XY sex chromosome system, with the Y chromosome being minute, as has been reported in several species of the sceloporine genera *Uta* (Pennock *et al.*, 1969) and *Sceloporus* (Cole, 1971a, 1971b, 1978). The minute Y was seen in some of the secondary spermatocytes examined from males of this species. The remainder of the spermatocytes presumably possessed
Fig. 2—Meiotic cells from male lizards. A) Diakinesis of *Leiocephalus raviceps* (the heteromorphic sex bivalent is indicated by an arrow); B) secondary spermatocyte from *Leiocephalus raviceps* (the presumed Y chromosome is indicated by an arrow); C) diakinesis of *Anolis homolechis*; D) secondary spermatocyte from *Anolis ponatus*.

the larger X chromosome, which is not distinguishable from the autosomal microchromosomes. Neither Gorman et al. (1967) nor Paull et al. (1976) mentioned sex chromosomes in other species of *Leiocephalus*, but slight heteromorphism in the microchromosomes easily might have been overlooked, and the heterogametic sex may not have been karyotyped in some cases.

Gorman et al. (1967) reported the karyotype of Haitian *Leiocephalus schreiberi* to consist of 12 metacentric macrochromosomes and 24 microchromosomes. Most iguanid genera that have been studied contain species with this 12 plus 24 karyotype, or a karyotype only slightly modified from that form. The 12 plus 24 karyotype is found in all of the major radiations of
iguanids, except the sceloporines, where all species (excluding the chromosomally diverse genus _Sceloporus_) have a 12 plus 22 karyotype. Some authors (Gorman et al., 1967; Paull et al., 1976; Bickham, 1984) have argued that the 12 plus 24 karyotype is ancestral for the family Iguanidae (and perhaps the entire suborder), although others (Cole, 1970, 1971b; King, 1981) have expressed differing opinions.

All _Leiocephalus_ species karyotyped to date have 12 metacentric macrochromosomes, and the same pattern is found in other tropidurine genera such as _Tropidurus_ and at least some members of the genus _Liolemaeus_ (Paull et al., 1976; Peccinini-Scale, 1981). _Leiocephalus_ karyotypes vary from the basic iguanid pattern only in the number of microchromosomes.

Paull et al. (1976) reported unpublished data of W. P. Hall from four unspecified species of _Leiocephalus_. Hall confirmed the _L. schreiberi_ karyotype in at least one other Hispaniolan species, but "found representatives of the Cuban branch of the genus" to have only 20 microchromosomes. Paull et al. (1976) did not indicate which Cuban species were karyotyped by Hall, but based on the karyotype, it would appear that neither of the two species examined by us were included in Hall's studies.

_Anolis._—We karyotyped two species of _Anolis_, and confirmed the karyotypes reported for these species by Gorman and Atkins (1968). Three male _A. homolechis_ were examined, and all showed a 2n = 28 karyotype with 14 biarmed macrochromosomes, and 14 microchromosomes. This karyotype was determined primarily from diakinesis cells, which had 14 bivalents (Fig. 2C).

One male _A. porcatus_ had a 2n = 36 karyotype with 12 biarmed macrochromosomes, and 24 microchromosomes (Fig. 1D). This karyotype is common among the alpha _Anolis_ (Gorman et al., 1967; Gorman and Atkins, 1968; Gilboa, 1975). No diakinesis arrays were found from this individual of _A. porcatus_, but haploid secondary spermatocytes showed the expected n = 18 karyotype (Fig. 2D).

_Ameiva auberi._—We karyotyped one juvenile female of this species, and found a diploid number of 50, as in all other members of the genus that have been karyotyped (Matthey, 1933; Gorman, 1970, 1973; Gilboa, 1975). The 13 largest chromosome pairs in _Ameiva_ are classified as macrochromosomes, although the size difference between macrochromosomes and microchromosomes is not particularly distinct. The karyotypes of _Ameiva_ species differ only in the number of biarmed chromosomes.
Gorman (1970) hypothesized that the all-acrocentric karyotype of the mainland species *Ameiva ameiva* is ancestral for the genus. The same karyotype also is found in *A. exsul* from Puerto Rico (Gorman, 1970). However, other Caribbean *Ameiva* that have been studied have partially biarmed karyotypes, and the biarmed condition is apparently restricted to species from the West Indies (Gorman, 1970; Gilboa, 1975; Peccinini-Seale, 1981). In two Caribbean species (*A. dorsalis* from Jamaica and *A. maynardi* from the southern Bahamas), only the two largest pair of chromosomes are biarmed, whereas in the Hispaniolan species *A. chrysoaema*, pairs 1, 5, and 8 are biarmed (Gorman, 1970).

We examined six cells from the Cuban *A. auberi*, and found that the five largest pair are biarmed, as well as three smaller pair of macrochromosomes, which we designated as pairs 7, 9, and 12 (Fig. 1E). Gorman (1970) suggested that the Caribbean radiation of the genus was derived from South American taxa having an entirely acrocentric karyotype, and that pericentric inversions arose in different combinations on the various islands. If this interpretation is correct, it would appear that *A. auberi* has rearranged its karyotype more extensively than other Caribbean *Ameiva* thus far studied.

**Acknowledgments**

For logistics, accommodations, and permission to work at Guantanamo Bay, we thank Lt. Bob Hines, Capt. Bruce Williams, and Chief Michael S. Potts. For assistance in collecting, we thank Linda K. Gordon, Lora Head, Karen McBeth, Robert Owen, Carl Phillips, Michael S. Potts, and Robin Ulrich. Fred Stangl organized our trip and worked out many of the original plans. Michael W. Haidak karyotyped some of the specimens used in the study. Ronald Van Den Bussche and Addison Wynn reviewed the manuscript, and we thank Ernest E. Williams for helpful correspondence. Laboratory work was supported by National Science Foundation Grant no. BSR 86-00646.

Crombie, Division of Amphibians and Reptiles, National Museum of Natural History, Smithsonian Institution, Washington, DC 20560. Received 23 February 1989, accepted 14 March 1989.
PUBLICATIONS OF THE MUSEUM
TEXAS TECH UNIVERSITY

Three serials of The Museum of Texas Tech University are published by Texas Tech University Press. Short research studies are published as Occasional Papers, whereas longer contributions appear as Special Publications. Papers of practical application to collection management and museum operations are issued in the Museology series. All are numbered separately and published on an irregular basis.

The preferred abbreviation for citing The Museum's Occasional Papers is Occas. Papers Mus., Texas Tech Univ.

Institutional subscriptions ($19/yr., typically 10 numbers issued per year) are available through Texas Tech University Press, Sales Office, Texas Tech University, Lubbock, Texas 79409-1057. Individuals can purchase separate numbers of the Occasional Papers for $2.00 each from Texas Tech University Press. Remittance in U.S. currency check, money order, or bank draft must be enclosed with request (add $1.00 per title or 200 pages of publications requested for foreign postage; residents of the state of Texas must pay sales tax on the total purchase price). Copies of the "Revised checklist of North American mammals north of Mexico, 1986" (Jones et al., 1986, Occas. Papers Mus., Texas Tech Univ., 107:1-22) are available at $1.25 each in orders of 10 or more.
